This applet is supposed to let you process a bunch of XML files. It supports replacing strings with strings, updating numeric attributes with a formula (you specify the formula in the file), processing meta-data, and writing new content to files. The applet allows you to set the number of concurrent processes it will run at a time (it currently uses only one), and you can save a list of file names, so you can work with a bunch of them at once. In the current version you can only process 'complete' tags in the XML files, e.g. you can only process one root tag that has a child tag. This is an artifact of the way XML files are interpreted. In fact, the way to process the content of the files is not really relevant, because what you replace is specified within the applet, so it's all up to you to pick which attribute to replace and which formula to apply to what. The applet is intended to be a tool for converting one set of .xml files to another, like you would use a batch processor to do. For example, if you already have a bunch of .xml files and want to replace all instances of "Vocoder Oscillator" with "Synth Oscillator". You can do that with the XMLBatchProcessor tool. At the moment, there are 2 source projects for the applet: 1. xmltool.exe - This is the main project of the application, it's a batch file which does the processing. It has the functionality to iterate over a list of XML files and has the ability to process 'partial' tags (like I said, currently). It has no special abilities and just changes files on the disk. The files don't even have to exist before the batch process is started. 2. xmlbap.exe - The Batch Application Project. This contains the code which parses the XML files into a .net object hierarchy that is then processed by the xmltool.exe project. I did this because I wanted to make this process configurable, and thus I could just have one xmlbap.exe solution instead of having two xmltool.exe solutions and a bunch of batch files. I think I also need to mention that you have to right-click the application icon, go to 'Run with' and select 'xmltool.exe' instead of 'xmlbap.exe' if you are using the

macro for converting the values of the numeric attributes of all items with the same name. macro for replacing the text 'hello' in all items with the text 'Bye'. macro for replacing the file at a given path with a .flac copy of the same file. Usage: Set the argument string for the conversion formula to the target string. The argument string is then applied to the numeric values of all items with the same name in all.xml files. Usage: Set the argument string for the conversion formula to the source string. The argument string is then applied to the numeric values of all items with the same name in all.xml files. Usage: Set the path to the target directory for all items with the same name in all.xml files. This directory will be created automatically. Version: The XMLBatchProcessor application was developed to be tool which lets you process a bunch of .xml file at once. The 'process' can be to replace a string with another string or convert values of numeric attributes by applying a conversion formula to them. This tool may come in handy, when for some reason you want to or have to change a bunch of preset files for one of the rs-met products. An example scenario could be: you have created a bunch of patches for Straightliner using your own.wav files as oscillator waveforms. These patches will have stored the relative paths of these wavefiles. Now you realize that the synth supports.flac and you want to replace those.wav files with their.flac counterparts. So you do. But in order for your patches to still work, you must now change the stored filenames in all those.xml files - no problem: invoke the XMLBatchProcessor, browse to your patch directory, set the program up to replace.wav with.flac and let it do its work. Of course, there might be completely different scenarios which are not necessarily related to patches for rs-met products at all. DISCLAIMER: This program will irreversibly change the content of a whole bunch of files - you use it at your own risk. Although there is a mechanism to automatically create a backup of the old files (they will be zipped to an archive before applying the processing), don't rely on this for sensitive data and use this tool with care. What's New In?

The XMLBatchProcessor is a simple batch processing tool which can be used to process a whole bunch of files at once. For details and examples, please see the readme.txt file. Usage: This tool can be used with all kinds of files, but for simplicity, this tool will be used with XML files. This program can be run from DOS prompt or directly from a DOS Shell script. A sequence of files can be specified on the command line using the --filename argument. They will be processed in the order they are listed. This argument is a kind of filter and can be used to exclude certain files or even to filter them based on their content. The --filename argument can also be used to specify the batch processing itself: the input files are read from the standard input and the program is processed one file at a time. The --save-raw-output argument can be used to write the output to a separate file. It's useful, if you want to extract only the interesting parts of the processed files. The --time-chunk argument can be used to specify a time range for which you want to process the files. This means you can process a whole bunch of files at once without having to sit there and do this for each file one by one. The --keep-properties argument can be used to keep the existing file properties intact. This might be handy, if you process a bunch of files with the same properties and you want to have the processed files keep those same properties. The --dry-run-before-processing argument can be used to see what the program will do before you actually apply it. This argument may be useful when you want to make sure the file properties are actually intact. The --help-examples argument can be used to see some example commands in detail. The --help argument can be used to see the complete usage of the program. Commands: The commands and arguments of this tool are all described in the help file. If you want to get a general idea of what you can do with this tool, you can try out these examples. Of course, you may want to try out some of your own commands and arguments. Command line syntax: cmd-line-syntax Description: The description is the help file - its contents may not be 100% up-to-date, but is very close to it. Usage: The usage of this command line argument is described in the description. Example: The examples can be seen in detail in the --help-examples argument. The examples can be seen in detail in the --help-examples argument. The examples can be seen in detail in the --help-examples argument. This command line argument lists all the arguments and their descriptions. Command line syntax: cmd-
