Coupled helices are the building blocks of helically architected polymers. Starting from the free standing single chain, they are capable of forming extended objects in which a continuous helical twist is preserved at finite length, thus uniting the processing of various shaped objects with the intrinsic rotational instability of the helical architecture. It has been shown that a single helical segment is stable to a torsion perturbation. However, the coupling of pairs of helices leads to a finite number of completely stable configurations and thus to a finite size of the absolutely stable helical state. We investigate the stability of helical structures and define a percolation threshold above which a helical pattern can be considered to be a stable structure. The critical size of stable helices strongly depends on the global parameters of the problem (equilibrium length, gap width and radius of curvature). The stability of helices can be measured as the ratio of the maximal eigenvalue of the stability matrix to the maximal eigenvalue of the Gaussian matrix, and the results are valid for arbitrary curvatures. The stability threshold and the structure of the marginally stable states are investigated by analytical approximations in three limits: thin and thick helices, rigidly coupled segments and rigidly coupled rings. I am the maintainer of the list, so any issues/questions etc, feel free to ask! ~~~ curiousgal If you don't mind me asking, why do you maintain it?
