Figure 8-1: Photoshop lets you manipulate digital images with a layer system. You can use multiple layers for overlays, transparency, and blending modes to create new images. Finding Utilities

The two utilities in the Photoshop Image Manipulation category in the Utilities window are: Blur Gallery: This app (see Figure 8-2) lets you adjust the blur and vignette effects. Unsharp Mask: This tool (see Figure 8-3) sharpens an image and lets you apply a variety of sharpening filters to the image. **Figure 8-2:** Use the Blur Gallery to simulate and apply blur, vignette, and desaturation effects. **Figure 8-3:** The Unsharp Mask features several sharpening filters. Downloading Your Photos Photoshop stores your images in separate compartments called bins. The bins are where you put all the images that you want to work on together. By default, the bin is called Untitled (Bin). The image you've opened will be in the Untitled (Bin) file folder. If you don't already have an image in a bin, you can create a new one. Choose File⇒New⇒Untitled (Bin) and follow the onscreen prompts to create a new bin (see Figure 8-4). **Figure 8-4:** Create a new bin in Photoshop using the New⇒Untitled (Bin) command. Syncing Photos When you import an image to Photoshop, it opens in the program with the initial auto-generated settings that Photoshop automatically applies to it. The image settings include options for adjusting brightness, contrast, shadows, and highlights. While you can change these settings, the initial settings are built into the image and cannot be changed. Instead of starting from scratch, use the Import Settings command to choose a preset or adjust the image settings. Choose File⇒Import Settings or press Ctrl+I. The dialog box shown in Figure 8-5 opens, letting you select an image, group, or folder. Selecting an image opens it and places it in the Open Image dialog box. **Figure 8-5:** Choose a preset or adjust image settings to start with. When the Import Settings dialog box opens, navigate to the image's location in the file tree, and select the image. The settings in the dialog box

To start, open the image that you'd like to edit or create a new one. In this tutorial, we're going to edit the picture that we saved in our previous tutorial. Open the image. Open the image with the Image ► Open dialog box. A dialog box will open. Place your cursor on the image to select the area. Click and drag to select the area that you want to edit. Click on the Edit ► Edit Image menu to open the Edit Image dialog box. In this dialog box, you can select the changes that you want to make to the image. Here, we will change the color to white and delete the outline of the image. Go to the Select tab and click on the color dropdown menu. A list will come up with a number of different colors to pick from. Make sure that White Color is selected by clicking on it or by pressing the V key on your keyboard. Press Ctrl+A (Command+A on a Mac) to select the selection of the image. Press Ctrl+D (Command+D on a Mac) to delete the selection. Press Ctrl+Backspace (Command+Backspace on a Mac) to delete the selection. You will notice that your selection has been deleted from the image. Go to the Options

tab and set the Fill to White. Go to the Crop tab and set the Crop to the shape of the head. The shape of the head has been cropped. Go to the Filters tab and select No Filter. Go to the Adjustments tab and select Brightness/Contrast. Go to the Lens tab. Go to the View tab and select the Type: Image Size setting. It shows you the different Size options available to you. There are four available Image Size options. From largest to smallest: Bicubic (best), Bicubic Sharper (almost best), Bicubic Smoother (almost worst), and Lazy Sharper. If you have an older computer, Bicubic Sharper is the best option. If you have a newer computer, Lazy Sharper is a great option. You can also use the default setting, which is Bicubic, which is the best option on all computers. 388ed7b0c7

$J_y=1$. Then the number of pairs (qubits per meter) $N = \mathcal{E} / \Lambda \pi$ can be computed by:

$$N = \frac{1}{\pi} \int_0^d \Phi(s) \exp[-2|s|^2] ds$$

The number of useful pairs is given by $N_{\text{eff}} = N/3 = \frac{1}{3\pi} \int_0^d \Phi(s) \exp[-4|s|^2] ds$

In Fig. [fig:coh_effect_on_distance] we report the effective number of pairs as a function of the source density η for $\sigma_+/\sigma_- = 1$ and $\sigma_+/\sigma_- = 2$. For the sake of comparison we also report the effective number of pairs for the independent case $J_{ij} = 0$. Since for independent emissions the number of pairs is exactly three times the number of useful pairs we see that, for a given source density, the entanglement partially compensates the distance loss. Interestingly enough for this particular case of $J_{ij} = 0$ the number of pairs increases with the source density, whereas for the entanglement case the opposite occurs. This result can be understood by considering the effect of the phase matching function on the probability amplitude of the photons emitted by the source. Using Eq. and we find

$$\begin{aligned} \Phi(s) &= \sum_{ij} \frac{\sigma_i \sigma_j}{(1 + i\sigma_-)^2} J_{ij} \exp\left[i\sqrt{3} \text{eff}(\mathbf{k}_i \cdot \mathbf{s} - \frac{1}{2} \mathbf{k}_i \cdot \mathbf{s})\right] \end{aligned}$$

[Xanthogranulomatous pyelonephritis. Apropos of a case]. Xanthogranulomatous pyelonephritis (XGP) is a histological type of non-specific inflammation, but its etiology remains unknown. The authors report a case in a 44-year-old woman with several years of progressive left-sided lumbar pain. Local explorations revealed a large renal mass and x-ray study showed a retroperitoneal mass. The tumor was removed and histology was consistent with xanthogranulomatous pyelonephritis. A review of the etiology and pathology of this disease is made and a differential diagnosis with malignant tumors, especially renal carcinoma, is discussed. A model based on an autosomal dominant trait with variable penetrance and epistasis to express a lethal phenotype. We develop a mathematical model for a mating structure and mating possibilities. An individual inherits a lethal recessive lethal (cautious) allele, which is epistatic in mating partners (e.g. her mate or her child). While the individual is autonomous in the reproduction process, her mate is her genetic parent. Individuals with the homozygous cautious allele (cc) are unable to mate and reproduce (they are dead). Individuals with the heterozygous allele (Cc) mate without restrictions; they can pass on the alleles to their children. While being cautious at reproduction, the offspring of Cc individuals is not lethal. This assures the spread of the Cc allele into the population. Individuals with the homozygous noncautious allele (c) may mate freely and can produce offspring that inherit the lethal allele. The penetrance of the cautious allele in the population is a key parameter for the evolution of this mating structure. If this penetrance exceeds a threshold value (which depends on the mutation rate and the fertility rate of the cautious allele, μ_0 and λ , respectively), individuals homozygous for the lethal allele die out of the population. In the absence of an allele for noncautious mating (e.g. if the cautious allele is fixed in the population), the system reduces to a F1 mating structure without epistasis in mating partners and without restrictions on reproduction. The mating structure can thus be seen as an example of a "sex-ratio" system. The lower the value of the penetrance, the higher the value of the required mutation rate for the evolution of the mating
