Rachis is designed as an Open-Source and cross-platform software for the arrangement of entities in a hierarchical system, and an interactive key for the entities found in that system. The GUI is implemented using wxWidgets and porting to systems with a wxWidgets port should be trivial. Rachis has evolved from Taxabase. It is (re)-written from scratch applying the lessons learned in the development of Taxabase. In general terms the main goals are better integration with the host operating system, better file formats that can be easily imported into applications like spreadsheets, and plugin support. Rachis has two key features: Interactive key for entities (aka referenced key): Rachis allows users to add/remove entities from the database in a convenient way. There are two main ways of acting on entities: Adding a field to the entity, if the entity doesn't have it already: Click on the "+" button, add the field using the dialog that pops-up, add a description if you like and press OK. The field will be filled in the popup window and shown on the entity. Selecting a field to add to the entity, and pressing Add: Click on the "Add" button, select the entity and press OK (if you have several you can select multiple entities using Shift+click and add the fields to all entities at once using Ctrl+click). The field will be filled in the popup window and shown on the entity. Removing fields from the entity, if the entity has them already: Click on the "-" button, click on the entity and press the OK button in the dialog that pops up. The field will be removed and shown on the entity. Enter / edit fields for entities: Rachis allows users to enter/edit fields for entities (also known as referenced key in some computer vision/shape recognition systems like the ones presented in [1], [2] or [3]). The functionality can be accessed either from the popup dialogs that show/edit the fields for entities, or from the context menu. Drag & drop support: Rachis makes the use of standard drag & drop features across applications easy and intuitive. All the references of the entities are kept (if the entities belong to a reference key, see below). Moving entities from one table to another (for example from shape-to-shape) can be very useful for a number of applications. Data Flow: Entities of the database can be shown in tables. These tables can be searched. Entities can be selected. They can be dragged from a table to another table. The primary purpose of Rachis is to provide a convenient way of managing the entities. It also allows for creating new entities (either by importing from another software, as described below), but this is a feature currently under development. By default the entities are stored in the database "Core" (an SQLite database containing most of the information). Rachis allows for migrating the entities to other databases (the location of the database that is 3a67dffeec
